

Esophageal Cancer Awareness Month

It's the Perfect Time to Talk to Us About Your Chronic Heartburn

There is a connection between heartburn and Esophageal Adenocarcinoma—one of the fastest growing cancers in America.

Chronic heartburn, also known as GERD, is a symptom of acid reflux that can lead to the development of precancerous yet harmless cells.

If left untreated, precancerous cells can lead to esophageal cancer.

Due to recent medical advances, physicians can now more accurately detect precancerous cells.

If found, these cells can typically be destroyed before they can progress to cancer.
